Creatine Phosphokinase Test

Creatine phosphokinase (CPK) is an enzyme in the body. It is found mainly in the heart, brain, and skeletal muscle. This article discusses the test to measure the amount of CPK in the blood.

How The Test Is Performed

- A blood sample is needed. This may be taken from a vein. The procedure is called a venipuncture.
- This test may be repeated over 2 or 3 days if you are a patient in the hospital.

How To Prepare For The Test

- No special preparation is needed most of the time.
- Tell your health care provider about any medicines you are taking. Drugs that can increase CPK measurements include amphotericin B, certain anesthetics, statins, fibrates, dexamethasone, alcohol, and cocaine.

How The Test Will Feel

You may feel slight pain when the needle is inserted to draw blood. Some people feel only a prick or stinging sensation. Afterward, there may be some throbbing.

Why The Test Is Performed

When the total CPK level is very high, it most often means there has been injury or stress to muscle tissue, the heart, or the brain.

Muscle tissue injury is most likely. When a muscle is damaged, CPK leaks into the bloodstream. Finding which specific form of CPK is high helps determine which tissue has been damaged.

This Test May Be Used To:

- Diagnose heart attack
- Evaluate cause of chest pain
- Determine if or how badly a muscle is damaged
- Detect dermatomyositis, polymyositis, and other muscle diseases
- Tell the difference between malignant hyperthermia and postoperative infection

The pattern and timing of a rise or fall in CPK levels can be significant in making a diagnosis. This is particularly true if a heart attack is suspected.

In most cases other tests are used instead of or with this test to diagnose a heart attack.

Normal Results

Total CPK normal values:
• 10 to 120 micrograms per liter (mcg/L)

Normal value ranges may vary slightly among different laboratories. Some labs use different measurements or test different samples. Talk to your doctor about the meaning of your specific test results.

**What Abnormal Results Mean**

High CPK levels may be seen in people who have:

- Brain injury or stroke
- Convulsions
- Delirium tremens
- Dermatomyositis or polymyositis
- Electric shock
- Heart attack
- Inflammation of the heart muscle (myocarditis)
- Lung tissue death (pulmonary infarction)
- Muscular dystrophies
- Myopathy
- Rhabdomyolysis

Other conditions that may give positive test results include:

- Hypothyroidism
- Hyperthyroidism
- Pericarditis following a heart attack

**Risks**

Risks associated with having blood drawn are slight but may include:

- Excessive bleeding
- Fainting or feeling light-headed
- Hematoma (blood accumulating under the skin)
- Infection (a slight risk any time the skin is broken)

**Considerations**

- Other tests should be done to find the exact location of muscle damage.
- Factors that may affect test results include cardiac catheterization, intramuscular injections, trauma to muscles, recent surgery, and heavy exercise.

**Alternative Names**

CPK test

About MedlinePlus

MedlinePlus is the National Institutes of Health's Web site for patients and their families and friends. Produced by the National Library of Medicine, the world's largest medical library, it brings you information about diseases, conditions, and wellness issues in language you can understand. MedlinePlus offers reliable, up-to-date health information, anytime, anywhere, for free.

You can use MedlinePlus to learn about the latest treatments, look up information on a drug or supplement, find out the meanings of words, or view medical videos or illustrations. You can also get links to the latest medical research on your topic or find out about clinical trials on a disease or condition.
